Reprint: Twenty Things to Do With a Computer

Seymour Papert; & Cynthia Solomon

Contemporary Issues in Technology and Teacher Education is an online journal. All text, tables, and figures in the print version of this article are exact representations of the original. However, the original article may also include video and audio files, which can be accessed online at http://www.citejournal.org
This report describes research done at the Artificial Intelligence Laboratory of the Massachusetts Institute of Technology. Support for the laboratory's education research is provided in part by the National Science Foundation under grant GJ-1049.

TWENTY THINGS TO DO WITH A COMPUTER

by Seymour Papert and Cynthia Solomon

When people talk about computers in education they do not all have the same image in mind. Some think of using the computer to program the kid; others think of using the kid to program the computer. But most of them have at least this in common: the transaction between the computer and the kid will be some kind of "conversation" or "questions and answers" in words or numbers.

In the real world computers are used in many different ways. Some are programmed to fly airplanes; not to tell a human pilot what to do, but to pull the levers with their own electro-mechanical effectors and to read the altitudes, airspeeds and what-not with their own electronic sensing devices. Computers are programmed to generate music or to condition dogs by ringing bells and delivering meat powder while the modern day Pavlov is happily asleep. Some computers are programmed to control lathes and milling machines in industrial plants; others generate pictures for animated film cartoons.

Why then should computers in schools be confined to computing the sum of the squares of the first twenty odd numbers and similar so-called "problem-solving" uses? Why not use them to produce some action? There is no better reason than the intellectual timidity of the computers-in-education community, which seems remarkably reluctant to use the computers for any purpose that fails to look very much like something that has been taught in schools for the past centuries. This is all the more remarkable since the computerists are custodians of a momentous intellectual and technological revolution. Concepts from the sciences of computation -- "cybernetics", "information theory", "artificial intelligence" and all its other names -- have deeply affected thinking in biology, psychology and even the philosophy of
mathematics. Machines from its engineering branches are changing our way of life. How strange, then, that "computers in education" should so often reduce to "using bright new gadgets to teach the same old stuff in thinly disguised versions of the same old way."

But our purpose here is not to complain of what other people have not done, but to tell of some exciting things you can do with the computer you have now or with the one you will be incited to get by the pages that follow. More than half the suggestions we are about to make have been implemented and tested in our elementary school teaching program. This does not imply that they are not of equal or greater value at other levels of education; on the contrary, we are convinced that they give a glimpse of the proper way to introduce everyone of whatever age and whatever level of academic performance, to programming, to more general knowledge of computation and indeed (we say courageously steeling ourselves for the onslaught) to mathematics, to physics and to all formal subjects including linguistics and music.

Each section of this paper describes something one can do with a computer. Most of these things-to-do assume that your computer can spin motors, activate electromagnets, switch lights, read the state of light sensitive cells and so on. The amazing fact is that it is very easy to make your computer do all these things! The last section of this paper says something about how to make it do so if it doesn't already. But while reading the paper you need not (and should not, it is a distraction) think about how the commands we describe will produce their effects. As you read on you will be learning a computer language called LOGO. In order to use a computer language you do not need to know how the computer works -- no more than you need to know how a human brain works in order to give a person instructions. In both cases you need only know how to describe what you want in an appropriate language.
1. Make a Turtle

The picture shows one of our turtles ... so-called in honor of a famous species of cybernetic animal made by Grey Walter, an English neurophysiologist. Grey Walter's turtles had life-like behavior patterns built into its wiring diagram. Ours have no behavior except the ability to obey a few simple commands from a computer to which they are attached by a wire that plugs into a control-box that connects to a telephone line that speaks to the computer, which thinks it is talking to a teletype so that no special system programming is necessary to make the computer talk to the turtle. (If you'd like to make a fancier turtle you might use a radio link. But we'd like turtles to be cheap enough for every kid to play with one.)

The turtle can send signals back to the computer. These signals appear to the computer just like the signals from a teletype -- so, again, no special system programming is necessary to make a turtle talk to a computer. Where do the signals come from? They are generated by sense organs attached to the turtle. Our turtles do not have a fixed set of sense organs. Rather, they have inlets into which one can plug wires to attach any sense organs one is clever enough to make. Touch
sensors, light sensitive cells and sound detectors are obvious examples that require very little cleverness. Accelerometers and tilt detectors lead to more sophisticated fun.

Turtles can have effector organs as well. The activities described here use only a simple one -- a pen located at the turtle's center, which can be lowered to leave a trace of the turtle's path, thus turning it into a remarkable geometric instrument.
2. Program the Turtle to Draw a Man

A bad way to use a turtle is to know just which character symbols will cause the turtle's motors to move. A better way is to design a good language. This means deciding on a set of intelligible commands and building these into the computer language. For example, we can type LEFT 90 on the console keyboard and thereby cause the turtle to rotate 90° about its central axis in the left (i.e., counter-clockwise) direction. Obviously this is better than having to figure, every time one wants to use the turtle, the number of steps of the stepping motors one needs to produce the desired movement and writing a complicated instruction to send out control characters to produce these steps.

The following diagram explains the main commands in our turtle language.

**TURTLE LANGUAGE**

At any time the turtle is at a particular place and facing in a particular direction. The place and direction together are the turtle's geometric state. The picture shows the turtle in a field, used here only to give the reader a frame of reference:

1. The triangular picture shows the direction.
2. The turtle advanced 50 units in the direction it was facing.
3. The turtle's position remained fixed. It rotated 90° to the left. So its direction changed.
4. The turtle advanced 150 units in its new direction.
5. The turtle rotated left 135°.
6. (Produces no visible effect. But the next FORWARD instruction will leave a trace.) The effect of PENDOWN is to put the turtle in a state to leave a trace: the pen draws on the ground.
To make the computer do anything more complicated you have to write a program. For example (using our language, LOGO, in a way that should be self-explanatory) one might type into the computer the following definition:

```
→ ↓ TO DRAW :DISTANCE
1 FORWARD :DISTANCE
2 BACK :DISTANCE
END
```

TO says that a definition follows.
DRAW is the command being defined.
:DISTANCE says that the command will have an input and that in the definition its name will be "DISTANCE".

Now if we type the command

```
DRAW 100
```

the computer will say to itself: "How do I DRAW? Well, the definition says, "TO DRAW 100, first go forward 100 units then go back 100 units and that's all." So if the turtle is in PENDOWN state it will draw a line and come back to its starting position. Now, using TO DRAW as a sub-procedure, let's give the computer a new command, TO VEE, by typing the following definition:

```
→ TO VEE :SIZE
1 LEFT 50
2 DRAW :SIZE
3 RIGHT 100
4 DRAW :SIZE
5 LEFT 50
END
```

A defined command can be used in defining new commands just as if it were a primitive LOGO term like FORWARD or LEFT.

The command

```
VEE 100
```

will now cause the turtle to draw V's as shown in the figures. The starting and finishing positions of the turtle are shown by the usual triangle.
Now

```
TO MAN :SIZE
1  VEE :SIZE
2  RIGHT 180
3  FORWARD :SIZE
4  VEE :SIZE
5  FORWARD :SIZE/2
```

We now use the previously defined command in making our new command. In other words TO DRAW was a sub-procedure of TO VEE; TO VEE is a sub-procedure of TO MAN.

MAN 100 will draw

MAN 10 will draw

Here are some other drawings the fifth grade kids made the turtle draw.

```
.MAN

MEN
```
3. Turtle Biology

To make the turtle more like a living creature we must give it behavior patterns. This involves using sense organs. A well conceived turtle should be very flexible in this respect: instead of fixed sense organs like real animals, it should have a number of sockets (we find that eight is good) into which you can plug any on-off device such as a micro-switch, or light detector or whatever you think up. Such devices are easy and cheap to make.

Let's give the turtle a ridiculously simple piece of behavior based on using 4 touch sensors which we shall call \textsc{fronttouch}, \textsc{backtouch}, \textsc{lefttouch} and \textsc{righttouch}. The behavior consists of going straight ahead until it touches the wall, turning back and so on.

The "and so on" illustrates the need for "loops" or "recursion" in the procedure we are about to write. To prepare yourself for the concept, consider the plight of a person who never fails to keep a promise and who has been tricked into saying, "I promise to repeat what I have just said."

\begin{itemize}
\item \textbf{TO MARCH}
  \begin{itemize}
  \item 1 TEST FRONTTOUCH
  \item 2 IFTRUE RIGHT 180
  \item 3 FORWARD 1
  \item 4 MARCH
  \item END
  \end{itemize}
\end{itemize}

- The TEST will be "TRUE" if \textsc{fronttouch} is "TRUE", i.e., if the front touch sensor is activated.
- \textsc{IFTRUE} depends on the TEST. The turtle does an about face if the front touch sensor is touching the wall.
- In any case the turtle takes a little step forward.
- \textsc{MARCH} is the name of this procedure. It is also used as a command in the procedure. This is recursion. When the computer gets this, it starts to carry out the directions on how TO MARCH. So, it starts again at line 1.
The next definition explains this idea in a way that might be clearer for people who are used to another style of programming. It also illustrates some flexibility in LOGO by showing other LOGO idioms to express the same idea:

```
TO MARCH
 1 IF FRONTOUCH RIGHT 180 ←
 2 FORWARD 1
 3 GO 1 ←
END
```

This is equivalent to lines 1 and 2 above.

"GO 1" instructs the computer to go to line 1.

A more interesting behavior is to go to the wall and circumnavigate the room. Getting the turtle to find the wall is easy: just as in MARCH. To make it follow the wall we use the important concept of feedback. The idea is this. Imagine yourself walking next to a wall on your left with your eyes closed. Every now and then you put out your left hand. If it does not touch the wall, you say to yourself, "I'm wandering into space, better turn left a little." If you do feel the wall you say (slightly perversely) "maybe I'm getting too close, better turn right a little." The result is that you will follow the wall perhaps in a slightly wavy line.

![Diagram of wall navigation](image)

Your Progress
Interestingly this procedure would make you circumnavigate a house walking on the outside. Watch what happens at the corner:

To circumnavigate the room from the inside one could use FRONTTOUCH to know when to turn. A small extension of the procedure could enable the turtle to find a door and escape from the room. Or explore a maze. Or ...

Using light sensors one can imitate a moth's flight to the candle, cause turtles to pursue one another or to engage in dances or fights, and ...
4. Make a Display Turtle

In our fifth grade class a turtle that walks on the floor is called a "turtle turtle". Another kind is called a "display turtle". This kind exists on a "scope" (i.e. Cathode Ray Tube, i.e. TV-like screen) as a picture just like the triangle we have used to illustrate the same commands, leaving a line of light as a trace when given the command PENDOWN. The disadvantage of the display turtle is that it cannot move physically about the world, touching, pushing and playing. But it has advantages for some purposes. One is that is is very fast and accurate. Another is that one can command it to draw a line which will last only for a stated length of time -- say a tenth of a second. Thus it can make moving pictures.

In LOGO the command

PEN :NUMBER
causes all lines to appear for :NUMBER tenths of a second. Thus
PEN 10
makes all lines last a second before vanishing.

The command

FLY
will cause a bird to move across the screen if the following procedure has been written, as well as a procedure TO BIRD, which draws a bird.

TO FLY ←
10 PEN 2
20 BIRD
30 FORWARD 5
40 WAIT 2 ←
50 FLY ←

This procedure draws a bird. The picture of the bird will last 0.2 seconds.

It waits 0.2 seconds. By this time the bird has vanished.

This causes the whole action to repeat as the machine gives itself the command FLY.
5. **Play Spacewar**

Spacewar is a famous computer game invented at M.I.T. in the days when display programming was new and unusual. Two people play it. On the "scope" appears two spaceships, together with background frills such as stars, the sun, etc. There are two players; each controls a spaceship and may cause it to turn, go forward, shoot out a stream of rockets. Whoever destroys the other ship, wins. The excitement of the game is increased by such dangers as getting caught by the sun's gravity and vanishing in a brilliant explosion.

When our fifth grade class visited M.I.T., they were caught up by the fun of playing the game. (It really is orders of magnitude better than non-computerized pin-tables.) But unlike most people, our children could go back to school the next day and get caught up by the even greater fun of programming their own versions of spacewar.
6. **Differential Geometry**

The "turtle language" provides a very remarkable formal system for describing many geometric objects; we think vastly superior to Cartesian coordinates as an introductory path into geometry. To see this let's study a very simple procedure, known in our fifth grade class as POLY. In its simplest form POLY has two inputs called "STEP" and "ANGLE". In LOGO it is written:

```
TO POLY :STEP :ANGLE
1  FORWARD :STEP
2  LEFT :ANGLE
3  POLY :STEP :ANGLE
END
```

The following pictures show the effect of invoking this procedure with different inputs: (the first input is the side size, the second is the angle)

```
POLY 150 120
```

```
POLY 75 60
```

```
POLY 4 3
```

```
POLY 300 156
```

```
POLY 150 144
```

```
POLY 75 40
```

```
POLY 150 144
```
7. Draw Spirals

To change the procedure called POLY so as to draw spirals we make a very small addition to line 3. We also change the name -- but that is of course unnecessary.

```
TO POLY :STEP :ANGLE
1 FORWARD :STEP
2 LEFT :ANGLE
3 POLY :STEP :ANGLE
END
```

```
TO POLYSPI :STEP :ANGLE
1 FORWARD :STEP
2 LEFT :ANGLE
3 POLYSPI :STEP+5 :ANGLE
END
```

POLYSPI 5 90

POLYSPI 40 60

POLYSPI 5 120

POLYSPI 5 121

POLYSPI 5 125
8. Have a Heart (and learn to DEBUG)

Making a procedure to draw a heart went through the following steps.

Step 1: Find something like making a heart that we know how to do.

   Idea: a triangle.

```
TO TRI :SIZE
  1 FORWARD :SIZE
  2 RIGHT 120
  3 FORWARD :SIZE
  4 RIGHT 120
  5 FORWARD :SIZE
END
TRI 100
```

Step 2: Make a plan to modify TRI. Idea: Make a procedure TO TOP.

```
TO TOP :SIZE
  1 SEG :SIZE/2
  2 RIGHT 180
  3 SEG :SIZE/2
END
TOP 100
```

Then replace line 1 in TRI by

1 TOP :SIZE.

This is easy but the result is

```
HEART WITH BUG
```

Step 3: Debug. Trying out this idea produced a bug. Why? Because replacing "FORWARD" by "TOP" in line 1 of TRI has side effects we did not anticipate! (And is therefore typical of almost all good ideas in almost all good projects.) To remedy this we must change line 2 as well; and while we are about it let's change the name to "HEART1".

```
TO HEART1 :SIZE
  1 TOP :SIZE
  2 RIGHT 30
  3 FORWARD :SIZE
  4 RIGHT 120
  5 FORWARD :SIZE
END
HEART1 100
```
Step 4: Consider: is this a good enough abstract model of a heart.
   No. Let's curve its sides. After a little debugging we get:

```
TO HEART2 :SIZE
1 TOP :SIZE
2 SEG 2*:SIZE 60
3 RIGHT 30
4 SEG 2*:SIZE 60
END

HEART2 100
```

MINITHEOREM: A heart can be made of four circular segments.
9. Growflowers

A computer program to draw this flower uses the geometric observation that petals can be decomposed (rather surprisingly!) as two quarter circles. So let's assume we have a procedure called TO QCIRCLE whose effect is shown by the examples. Some of them show initial and final positions of the turtle, some do not.

QCIRCLE 50

QCIRCLE 100

Now let's see how to make a petal.

TO PETAL :SIZE
1 QCIRCLE :SIZE
2 RIGHT 90
3 QCIRCLE :SIZE
END

TO FLOWER :SIZE
1 PETAL :SIZE
2 PETAL :SIZE
3 PETAL :SIZE
4 PETAL :SIZE
END

TO STEM :SIZE
1 RIGHT 180
2 FORWARD 2*:SIZE
3 RIGHT 90
4 PETAL :SIZE/2
5 FORWARD :SIZE
END
PLANT 50

TO PLANT :SIZE
1 PEN Down
2 FLOWER :SIZE
3 STEM :SIZE
4 PEN Up
END

Now let's play a little.

TO HEXAFLOWER :SIZE
1 RIGHT 90
2 FORWARD 4*:SIZE
3 PLANT :SIZE
4 FORWARD :SIZE-
5 RIGHT 30
6 HEXAFLOWER :SIZE
END
10. Make a Movie

We describe how to make a very simple movie, in which the whole plot consists of a flower growing.

A flower can be drawn as well by the physical turtle described in Thing No. 1 as by a display turtle. Movies need a display turtle. The following commands in LOGO allow us to take advantage of a special feature of CRT drawings -- their ability to vanish! We recall that the command
PENDOWN
causes the turtle to leave a trace. The commands
PEN 50 (or PEN 10 etc.)
cause a trace that will stay for 50 tenths of a second (or 10 tenths of a second etc.) and then vanish. The command
WIPE
causes everything to vanish instantly.

Now let's try making successive frames of our little movie. First we do it by direct commands, rather than writing a new procedure.

PENDOWN
PLANT 5
WIPE
PLANT 10
WIPE
PLANT 30 etc.

This can be automated slightly by

PEN 50
PLANT 10
PLANT 20
: : : : :

This causes the picture to vanish after 5 seconds. So WIPE is not needed.

We give the commands PLANT 10, PLANT 20, PLANT 30 immediately after the previous picture vanishes.

To automate the process further we build a procedure around the central action command:

PLANT : SIZE
WAIT 5

A pause of half a second occurs, so that the next round does not rush in before the previous plant is seen. PEN 5 would be chosen to match WAIT 5.

Now make some more exciting movies!
A superprocedure to issue these commands will be called MOVIE. It will make successive frames appear at half second intervals

FRAME 1; PLANT 10  FRAME 2; PLANT 20  FRAME 3; PLANT 30

To command itself recursively at any given time it must know the appropriate input for PLANT. It also needs to know its frame number so as to know when to stop. We notice that remembering the frame number eliminated the need to remember separately the input to PLANT -- this is merely the frame number multiplied by 10. So the little movie program is:

TO MOVIE :THISFRAME :ENDFRAME
1 IF :THISFRAME= :ENDFRAME STOP
2 PLANT :THISFRAME*10
3 MOVIE :THISFRAME+1 :ENDFRAME
END

The meaning of these inputs is explained below.

HOW TO THINK ABOUT THE INPUTS

Picture of the Inputs

:THISFRAME is like a moving clock. It ticks up one after each frame.

STOP AT 6

:ENDFRAME is like a time posted up at the beginning of the show to tell the projectionist when to stop.

We think of a movie as a process. As it goes on we need to know two things: where we are and where we are going. The two inputs are set up for this. The first is :THISFRAME. It starts at 1 and increases by 1 on each round. It is the frame number. The second input remains constant during the showing of the movie.
11. Make A Music Box and Program A Tune

A music box is a device for making sound under control of a computer. Our style of music box "listens in" to the signals sent by a computer to a teletype. Just as the teletype "decodes" them as instructions to print particular characters, and the turtle decodes them as movements, the music box decodes them as instructions to emit particular sounds. It is only a slight technical frill to give the music box several "voices" that will play simultaneously.

One (very bad) way to make the computer play Frere Jacques would be to write the following LOGO procedure:

```
TO FJ
  PRINT "AAAICCCIEEE!AAAIAAAICCCIEEIEAAAEEF!H HHHHEEEF!HHH..."
END
```

A better approach is to program the computer to accept descriptions of music in a good notation. An example is the following (which is one of several we are trying experimentally).

This notation and many of the ideas about the musical aspect of our work is due to Terry Winograd and Jeanne Bamberger.

Our music box can play a five octave range of notes, with as many as four at a time. One octave is chosen as the base, and its twelve chromatic tones are numbered 1 through 12. Notes in the next octave up can be indicated either by continuing beyond 12 or by using the sign "!". Thus 13 and 1! represent the same note. The LOGO command SING takes a sequence of notes as input and plays them in order. Thus SING "! ! 3! 5! 6! 8! 10! 12! 11!" will cause a major scale to be played.

To add rhythm to the tune we use a LOGO operation MUSIC which takes two inputs: one a sequence of notes, the other a sequence of durations and combines them in the obvious way.

Now we use LOGO (following Terry Winograd) to write a better Frere Jacques procedure.
TO FRERE1
1 SING MUSIC OF "1! 3! 5! 11!" "2 2 2 2"
END

TO FRERE2
1 SING MUSIC "5! 6! 8!" "2 2 4"
END

TO FRERE3
1 SING MUSIC '8! 10! 8! 6! 5! 11!" "1 1 1 2 2"
END

TO FRERE4
1 SING MUSIC "1! -8! 11!" AND "2 2 4"
END

TO FREREJACQUES
1 .FRERE1
2 FRERE1
3 FRERE2
4 FRERE2
5 FRERE3
6 FRERE3
7 FRERE4
8 FRERE4
9 FREREJACQUES
END
12. Play with Semi-Random Musical Effects and then Try Serious Composing

Following Winograd again, we write a procedure, called RANDOMSONG, that will select randomly from a given set of tones. Trying it with different inputs produces very different musical effects. Thus RANDOMSONG "2 4 7 9 11" is described as "oriental" while RANDOMSONG "1 3 5 6 9 11" is described as "spooky".

Then you can try making some effects of your own. And after a while, you may like to write a piece of music with real structure. Many people would like to try their hand at musical composition, but cannot play well enough to hear their ideas. If you are one of them, this is your chance. The music box is an obedient orchestra that will play precisely whatever you can describe to it.
13. **Computerize an Erector Set Crane and Build a Tower of Blocks**

A turtle is driven by two motors. Detached from the rest of the turtle the motors can pull strings that can work any mechanisms. For example a crane built of erector set parts.

To pick up objects make a grab -- or use an electro-magnet. Make a pile of iron discs, one on top of the other. Program the computer and crane and magnet to play tower of Hanoi.
14. Make a Super Light Show

The school computer should have a large number of output ports to allow the computer to switch lights on and off, start tape recorders, actuate slide projectors and start and stop all manner of little machines. There should also be input ports to allow signals to be sent to the computer. We leave to your imagination the possibilities that this opens of making "interactive environments" for the next school festivity or even more solemn purposes.

In a similar spirit, but with a little more work, make an array of light bulbs to display the news of the day like they do it in Times Square. Or generate funny cartoons on the light bulb array. Or put up the scores at ball games and track events.

```

```

SUPERPEACE
15. Write Concrete Poetry

Perhaps we have carried too far our reaction against using computers to write symbols on teletype paper. Here are some examples of teletype output from procedures simple enough for the first weeks of a fifth grade course. We use teletype pictures as an initiation project to learn the very basic principles of using the computer, the terminal, the procedure definition idiom, the ritual for editing procedures and so on. Writing a random sentence generator made a girl exclaim: "So that's why we call words 'nouns' and 'verbs'." What she meant was: for the first time I see a use for classifying words.

THE FUNNY PROF TALKED WHILE THAT COOL KID KISSED . . .
SOME FUNNY PROF WALKED BUT A BEAUTIFUL KID CLAPED . . .
A WILD DONKEY KISSED WHILE THE FUNNY PROF CLAPED . . .
SOME GROSS PROF WALKED ALTHOUGH SOME COOL KID HUMMED . . .

?HAIKU

XXX XXX
XXX XXX

D D D
D D D
X X X

DOGS BY FIFTH GRADERS AT BRIDGE
16. **Try C.A.I. and Psychology**

A slight extension of the sentence generator idea leads to generating mathematical sentences that are **true** (as well as grammatical) though somewhat boring. For example:

```
TO RANDOMSUM
  1 MAKE
    NAME "NUMBER1"
    THING RANDOM
  2 MAKE
    NAME "NUMBER2"
    THING RANDOM
  3 MAKE
    NAME "SUM"
    THING :NUMBER1+:NUMBER2
  4 TYPE (SENTENCE :NUMBER1 "+" :NUMBER2 "=" :SUM)
  5 RANDOMSUM
END
```

The effect is something like

\[ 7 + 4 = 11 \]
\[ 3 + 2 = 5 \]
\[ 9 + 6 = 15 \]

and so on.

A slight modification will cause the computer to print something like

\[ 7 + 4 = ? \]

and wait for a human victim to type something in order to insult him if he fails to give the appropriate answer. For example:

\[ 7 + 4 = ? \] (Computer)
\[ ELEVEN \] (Victim)
\[ IDIOT, THE ANSWER IS 11 \] (Computer)

Even when the procedure has been modified to accept "ELEVEN" we can still tease the victim:

\[ 7 + 4 = ? \]
\[ ELEVEN \]
\[ DON'T THINK YOU ARE SMART, YOU TOOK MORE THAN 2 SECONDS. \]

By taking the timing idea more seriously one can do endless experiments to find out such facts as: which multiplications are hardest (for example:
1 X 1 is very easy but one might disagree about whether 7 X 9 is easier than 8 X 6). Or if one gets bored with teaching arithmetic one can teach children how to estimate lengths of time, to recognize rhythmic patterns and so on endlessly.

The conclusion from all this is that we have at last discovered the true role of C.A.I. in education. Writing C.A.I. programs is one of the twenty best projects for the first semester of a fifth grade computer science course!

In a similar spirit it's fun to do "optical illusion" experiments with the display turtle.
17. Physics in the Finger-Tips

We begin by inviting the reader to carry out the illustrated experiments -- or to recall doing something similar.

One of the goals of this unit of study will be to understand how people do this and particularly to understand what properties of a human being determine what objects he can and what objects he cannot balance.

A "formal physical" model of the stick balancing situation is provided by the apparatus illustrated next:
TURTLE KEEPS ROD FROM FALLING
BY MOVING FORWARD AND BACK.
POTENTIOMETER IN HINGE PROVIDES
INFORMATION FOR FEEDBACK.

A computer controlled version replaces the track and the child by a turtle with the angle sensor plugged into its sensor socket. A simple minded procedure will do a fair amount of balancing (provided that the turtle is fast!!):

TO BALANCE
1 TEST ANGLE > 10
2 IFTRUE FORWARD 8
3 TEST ANGLE < -10
4 IFTRUE BACK 8
5 WAIT 1
6 BALANCE
END

This procedure is written as part of a project plan that begins by saying: neglect all complications, try something. Complications that have been neglected include:

(1) The end of the line bug.

(2) The overshoot bug.
(Perhaps in lines 2 and 4 the value 8 is too much or too little.)

(3) The Wobbly Bug
The TEST in the procedure might catch the rod over to the left while it is in rapid motion towards the right. When this happens we should leave well alone!
One by one these bugs, and others can be eliminated. It is not hard to build a program and choose constants so that with a given setting of the movable weight, balance will be maintained for long periods of time.

**Feeding Energy**

Again we begin with some finger-tip physics by considering some toys:

- **YO-YO**
- **CLACKERS**
- **SWING**
- **PENDULUM**

All these systems will run down unless supplied with energy. How is the energy fed in? A good starting system is the clock pendulum on a rigid rod.

A linear actuator or one of the rotating joints can be used as a "pusher". A simple experiment will show the need for a good phase relationship. When this is understood, proceed to the flexible string and finally the interesting case of the swing in which the source of energy is carried by the pendulum.
A mechanical YO-YO player provides a different setting for similar principles and is an impressive example of a "skill" that can really be achieved quite easily by machines. Moreover it opens up a huge vista of challenging problems. Causing the YO-YO to SLEEP is a feasible hard project in our context. The more elaborate tricks like WALKING-THE-DOG or ROUND-THE-WORLD would probably succumb, but would need a lot of work and ingenuity.
18. Explain Yourself

Building machines to balance sticks did not actually answer the original question about why people can balance broom-sticks but not toothbrushes. What property of people determines how long (or short) a stick one can balance? The answer is: reaction time! Now go back to the balancing machines to give them reaction times rather like those of people (which you will find out by carrying idea number 16 a little further). How good a model can you make of a person? Does this explain you -- or at least explain one of your characteristics? Could similar models explain other human characteristics?
19. **Puppets**

The computer controls enough motors to pull enough strings to manipulate the desired number of marionettes. Like many of these projects, this one has this great educational property: some effect can be obtained by extremely simple means; extra effort will produce more exciting effects; and to emulate a skilled human puppeteer will require a very thorough understanding of the geometric and dynamic principles of movement.
20. Recursion Line

Think up twenty more things to do.
Epilog: How To Make Those Things Happen

Most of the devices we have mentioned are extremely simple and much cheaper than teletypes. The hardest problem has been getting the computer to communicate with the device. The approach we have developed centers around the concept of a "universal controller". This we define as a black box which looks to the computer like a teletype. So, to use it you would program the computer to print a piece of text which might read "!!(!!(!!(!!)!!")

knowing that the controller will turn "!" and "(" into turtle signals whose effect will be to cause forward and left steps respectively. Thus any programming language, running on any operating system (including commercial time sharing services) can be used to control a turtle.

In our image of a school computation laboratory, an important role is played by numerous "controller ports" which allow any student to plug any device into the computer. The ports are protected by fuses and suitable interfaces so that little harm will be done if anyone carelessly puts the main voltage into a computer output port. The laboratory will have a supply of motors, solenoids, relays, sense devices of various kinds, etc., etc. Using them the students will be able to invent and build an endless variety of cybernetic systems.

This is not the place to discuss strictly practical problems like where to buy good motors. We do, however, expect that very soon someone will supply a full range of suitable things. In any case we would be happy to provide advice and information.

On the Cost of Computation in Schools

A final word about the cost of doing all this. Turtles, music boxes, computer controlled motors and the like are less expensive than teletypes. Displays are slightly more expensive but becoming rapidly cheaper. So if computers are being used in a school, there is no good economic argument for accepting the narrowness of the pure teletype terminal.
Some school administrators and town politicians still consider the cost of using computers at all as too high. If you are engaged in battles on this point, write to LOGO INFORMATION to be briefed on the latest ideas and prices of equipment. At the moment a good estimate of what computation ought to cost is $30 per student per year, for one hour per student per week of terminal time. This is based on the assumption that several hundred students will be involved. The price could be halved within a year if several hundred schools would commit themselves to installing identical systems. Only inertia and prejudice, not economics or the lack of good educational ideas, stand in the way of providing every child in the world with the kind of experience of which we have tried to give you some glimpses. If every child were to be given access to a computer, computers would be cheap enough for every child to be given access to a computer.
